1 Abstract

This paper redefines the transition condition from discomfort to update in Future Convergence Theory (FCT), which has not been formally established in previous works. We introduce a new structural concept, the *Observation Phase*, to provide a unified description.

Contrary to conventional interpretations, discomfort is not treated as a temporal trigger. Instead, it is defined as an observed interference pattern within a semantic tensor field. Furthermore, criticality is not something that emerges over time, but rather a structural property that exists simultaneously at the moment a configuration is presented.

2 Definition of Observation Phase

We define the observation phase Φ as the triplet:

$$\Phi = (R, C, H) \tag{1}$$

where:

- R: Resolution
- C: Constraint Sensitivity
- H: Fixed-Point Horizon

The observation phase determines how a semantic tensor field is interpreted in terms of scale, constraint density, and future reference range.

3 Redefinition of Discomfort

Discomfort D is not a subjective feeling but is defined as:

$$D = \Delta\mathcal{I}(T) \tag{2}$$

where $\Delta\mathcal{I}(T)$ represents the interference differential within the semantic tensor field. Thus, discomfort is:

> The observed structural difference arising from interference between semantic tensors.

4 Principle of Critical Simultaneity

Conventional models treat discomfort as a cause of updates. However, we propose:

> Criticality does not emerge temporally but exists structurally at the moment a configuration is presented.

Given a structure S, the relationship between:

- the current structure C
- the future fixed point F

is already geometrically determined. Therefore, the necessity of update is not a temporal process, but a structural relation.

5 Redefinition of Update

Update is not a process but is defined as:

$$C \to C' \tag{3}$$

This is not a continuous transformation but:

> A phase transition between distinct fixed points.

6 Observation Phase and Criticality

For the same structure S, perception varies depending on Φ:

- Low phase: appears consistent
- Medium phase: discomfort emerges
- High phase: structural inconsistency is recognized

- High future horizon: immediate criticality is observed

Thus:

> Criticality always exists structurally, but its manifestation depends on the observation phase.

7 Final Formulation

We summarize the theory as:

> Discomfort is the interference pattern through which the entire meaning structure, including future fixed points, is exposed as self-inconsistency in the present, and criticality is an intrinsic geometric property of that structure.

8 Conclusion

This work unifies:

- discomfort
- update
- criticality
- observation

into a single structural framework.

As a result, Future Convergence Theory transitions from a temporal causal model to a geometric theory of semantic tensor fields.

Supplementary Chapter: Observational Phase Transition and Constraint-Coordinate Dynamics

Definition 1 (Observational Phase)

The observational phase ϕ is defined as the projection structure applied to the semantic tensor M under a constraint coordinate system C:

$$\phi := \mathcal{P}_C(M)$$

Definition 2 (Future-Aligned Phase)

The future-aligned phase ϕ^* is defined as the stable phase selected by the future convergence function $\Lambda(T)$:

$$\phi^* := \arg\min_{\phi} \ \mathcal{E}_\Lambda(\phi)$$

Proposition 1 (Emergence of Discomfort)

Discomfort is defined as semantic interference between the current observational phase ϕ_i and the future-aligned phase ϕ^*:

$$\exists x \in M \quad \text{s.t.} \quad \phi_i(x) \neq \phi^*(x)$$

Proposition 2 (Phase Transition Condition)

A phase transition $\phi_i \to \phi_j$ occurs when:

$$\mathcal{I}(M, \phi_i, \phi^*) > \mathcal{S}(\phi_i)$$

Proposition 3 (Non-Generative Nature of Transition)

Phase transitions are not generative but reveal pre-existing phase structures:

$$\phi^* \in \Phi(M)$$

Proposition 4 (Redefinition of Critical Point)

The critical point is defined as:

$$\mathcal{I}(M) = \mathcal{S}(\phi_i)$$

This represents the boundary where phase differences become observable.

Proposition 5 (Diversity as Phase Variation)

Diversity is defined as variation in observational phases:

$$\text{Diversity} = \{\phi_k(M) \mid C_k\}$$

Proposition 6 (Emergent Ethics)

Ethics is defined as the directional gradient toward future alignment:

$$\text{Ethics} \propto \nabla_\phi \left(-\mathcal{E}_\Lambda(\phi)\right)$$

Proposition 7 (Origin of Evil)

Evil is defined as fixation at a phase despite the existence of a reachable transition:

$$\exists \phi^* \text{ reachable}, \quad \phi = \phi_i \text{ fixed}$$

Proposition 8 (Responsibility Layer)

Responsibility is defined at:

- Phase selection layer
- Update acceptance layer

$$\text{Responsibility} := \mathcal{R}(\text{selection}, \text{acceptance})$$

Proposition 9 (Inevitability of Discomfort)

$$\forall \phi_i \neq \phi^* \Rightarrow \mathcal{I} > 0$$

Proposition 10 (Hierarchical Observational Phases)

$$\phi^{(low)} \subset \phi^{(mid)} \subset \phi^{(high)}$$

Proposition 11 (Unified Transition Principle)

$$\phi_i \to \phi^* \iff \mathcal{I}(M, \phi_i, \phi^*) > \mathcal{S}(\phi_i)$$
$$\phi^* \in \Phi(M)$$

Conclusion

Observational phase transition is the selective actualization of a pre-existing phase structure, triggered when interference with a future-aligned phase exceeds the stability of the current phase.

Formalization of Interference, Stability, and $\Lambda(T)$ Coupling

Definition 12 (Semantic Tensor Field)

Let M be a semantic tensor field defined over a domain Ω:

$$M : \Omega \to \mathbb{R}^n$$

Definition 13 (Phase Projection)

Each observational phase ϕ is defined as a projection operator:

$$\phi(M) := \mathcal{P}_C(M)$$

Definition 14 (Interference Functional)

The interference $\mathcal{I}$ between ϕ_i and ϕ^* is defined as:

$$\mathcal{I}(M, \phi_i, \phi^*) := \int_\Omega \|\phi_i(M(x)) - \phi^*(M(x))\|^2 \, dx$$

This represents the squared deviation across the semantic field.

Definition 15 (Phase Stability)

Phase stability $\mathcal{S}(\phi_i)$ is defined as resistance to perturbation:

$$\mathcal{S}(\phi_i) := \int_\Omega \|\nabla \phi_i(M(x))\|^2 \, dx$$

Alternatively, in discrete form:

$$\mathcal{S}(\phi_i) := \sum_{x \in \Omega} w(x) \cdot \mathrm{Var}[\phi_i(M(x))]$$

Definition 16 ($\Lambda(T)$ Coupling Energy)

Define the future convergence energy:

$$\mathcal{E}_\Lambda(\phi) := \int_\Omega \|\phi(M(x)) - \Lambda_T(M(x))\|^2 \, dx$$

where Λ_T is the future convergence mapping:

$$\Lambda_T : M \to M$$

Proposition 12 (Phase Transition Criterion)

$$\phi_i \to \phi^* \iff \mathcal{I}(M, \phi_i, \phi^*) > \mathcal{S}(\phi_i)$$

Proposition 13 (Consistency with $\Lambda(T)$)

$$\phi^* = \arg\min_\phi \mathcal{E}_\Lambda(\phi)$$

Thus:

$$\mathcal{I}(M, \phi_i, \phi^*) = \mathcal{E}_\Lambda(\phi_i) - \mathcal{E}_\Lambda(\phi^*)$$

Proposition 14 (Unified Dynamics)

The phase evolution can be written as:

$$\frac{d\phi}{dt} = -\nabla_\phi \mathcal{E}_\Lambda(\phi)$$

Conclusion

Interference, stability, and future convergence are unified as an energy-driven phase selection system over the semantic tensor field.
